Statistical Methods for Discrete Response, Time Series, and Panel Data (W271): Group Lab 3

Shishir Agarwal, Vasanth Ramani, Vineetha Nalini

U.S. traffic fatalities: 1980-2004

In this lab, you are asked to answer the question "Do changes in traffic laws affect traffic fatalities?" To do so, you will conduct the tasks specified below using the data set *driving.Rdata*, which includes 25 years of data that cover changes in various state drunk driving, seat belt, and speed limit laws.

Specifically, this data set contains data for the 48 continental U.S. states from 1980 through 2004. Various driving laws are indicated in the data set, such as the alcohol level at which drivers are considered legally intoxicated. There are also indicators for "per se" laws—where licenses can be revoked without a trial—and seat belt laws. A few economics and demographic variables are also included. The description of the each of the variables in the dataset is come with the dataste.

```
library(foreign)
library(gplots)
library(ggplot2)
library(dplyr)
library(corrplot)
library(lattice)
library(plm)
library(viridis)
library(tsibble)
library(forecast)
library(forecast)
library(gridExtra)
```

Exercises:

1. (30%) Load the data. Provide a description of the basic structure of the dataset, as we have done throughout the semester. Conduct a very thorough EDA, which should include both graphical and tabular techniques, on the dataset, including both the dependent variable totfatrte and the potential explanatory variables. You need to write a detailed narrative of your observations of your EDA. Reminder: giving an "output dump" (i.e. providing a bunch of graphs and tables without description and hoping your audience will interpret them) will receive a zero in this exercise.

```
#load data
load('driving.RData');driving.df <- data

#check rows and columns
dim(driving.df)</pre>
```

The Dataset is panel data, that contains observations about different US states from year 1980 to 2004. There are 1200 observations in total, with 56 columns. The data has 25 observations each, one per year, from 48 continental states except state ids 2,9 and 12 (which we will later identify as Alaska, District Of Columbia and Hawaii that are not part of continental US States). All variables are observed for all states and over all time periods, hence the panel is balanced. Important variables are:

Panel Index

year: 1980 through 2004

state: numeric id of 48 continental states, ordered alphabetically, ranging from 1 to 51.

Dependent Variable

totfatrte: total fatalities per 100,000 population by year by state. Values range from 6.2 to 53.32

Speed Limit Variables

sl55: 1 if speed limit == 55 for the whole year. If the law was in effect only during part of the year, it is set to fractions of 12. This applies for all indicator variables.

sl65: 1 if speed limit == 65 sl70: 1 if speed limit == 70 sl75: 1 if speed limit == 75 slnone: 1 if no speed limit sl70plus: sl70 + sl75 + slnone

Drinking Laws

minage: minimum drinking age, ranges from 18 years to 21 years.

zerotol: 1 if zero tolerance law was in effect, and 0 if not. If the law was in effect only during part of the year, it is set to fractions of 12.

bac10: 1 if blood alcohol limit .10 in effect, and 0 if not. Fractions used to denote partial years, as

bac08: 1 if blood alcohol limit .08 in effect, and 0 if not. Fractions used to denote partial years, as

per se: 1 if administrative license revocation (per se law) in effect, and 0 if not. Fractions used to denote partial years, as above.

Seatbelt Laws

sbprim: 1 if primary seatbelt law was in effect, 0 otherswise. There are no fractions in this variable. sbsecon: 1 if secondary seatbelt law was in effect, 0 otherswise. There are no fractions in this variable.

seatbelt: 0 if none, =1 if primary, =2 if secondary. There are no fractions in this variable.

Age iimit Laws

gdl: 1 if graduated drivers license law was in effect, and 0 if not. Fractions used to denote partial years, similar to speed limit.

Demographic variables

statepop: state population by year by state. Values range from 453,401 to 35,894,000 vehicmiles: vehicle miles traveled, billions. Values range from 3.7027 to 329.6 unem: unemployment rate, percent. Values range from 3.2 to 18 perc14_24: percent population aged 14 through 24. Values range from 11.7 to 20.3 vehiclemilespc: vehicle miles driven per capita. Values range from 4,372 to 18,390

Year Dummy

Dummy variables d80 - d04 indicating years

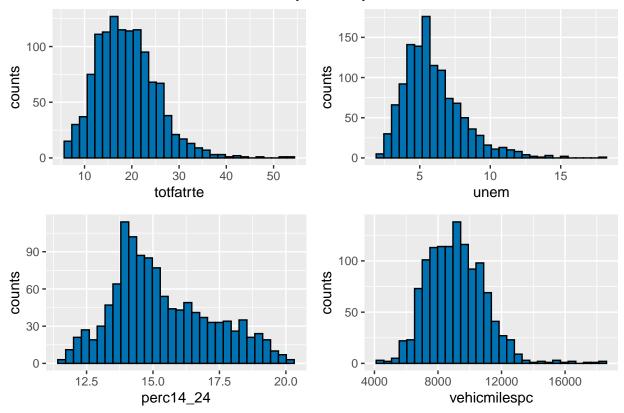

It will be useful to add more context around the state information, in addition to the state id. Since we know the id is alphabetical, we get the aphabetical list of US states with two letter abbreviated code, and match with the state variable in fatality data.

```
#get state name
us.states = read.csv("usstates.csv", header = TRUE, sep = ",", dec = ".")
data.with.name <- merge(data, us.states, by=c("state", "state"))</pre>
```

To start EDA, we perform univariate analyses of important variables fatality rate, unemployment, % of younger population, and vehiclemilespc to examine the distribution.

```
totfatrte.hist <- ggplot(driving.df, aes(x = totfatrte)) + geom_histogram(bins = 30, fill="#unem.hist <- ggplot(driving.df, aes(x = unem)) + geom_histogram(bins = 30, fill="#0072B2", comperc14_24.hist <- ggplot(driving.df, aes(x = perc14_24)) + geom_histogram(bins = 30, fill="#0072B2", comperc14_24.hist <- ggplot(driving.df, aes(x = vehicmilespc)) + geom_histogram(bins = 30, fill="#0072B2", comperc14_24.hist <- ggplot(driving.df, aes(x = vehicmilespc)) + geom_histogram(bins = 30, fill="#0072B2", comperc14_24.hist <- ggplot(driving.df, aes(x = vehicmilespc)) + geom_histogram(bins = 30, fill="#0072B2", comperc14_24.hist <- ggplot(driving.df, aes(x = vehicmilespc)) + geom_histogram(bins = 30, fill="#0072B2", comperc14_24.hist <- ggplot(driving.df, aes(x = vehicmilespc)) + geom_histogram(bins = 30, fill="#0072B2", comperc14_24.hist <- ggplot(driving.df, aes(x = vehicmilespc)) + geom_histogram(bins = 30, fill="#0072B2", comperc14_24.hist <- ggplot(driving.df, aes(x = vehicmilespc)) + geom_histogram(bins = 30, fill="#0072B2", comperc14_24.hist <- ggplot(driving.df, aes(x = vehicmilespc)) + geom_histogram(bins = 30, fill="#0072B2", comperc14_24.hist <- ggplot(driving.df, aes(x = vehicmilespc)) + geom_histogram(bins = 30, fill="#0072B2", comperc14_24.hist <- ggplot(driving.df, aes(x = vehicmilespc)) + geom_histogram(bins = 30, fill="#0072B2", comperc14_24.hist <- ggplot(driving.df, aes(x = vehicmilespc)) + geom_histogram(bins = 30, fill="#0072B2", comperc14_24.hist <- ggplot(driving.df, aes(x = vehicmilespc)) + geom_histogram(bins = 30, fill="#0072B2", comperc14_24.hist <- ggplot(driving.df, aes(x = vehicmilespc)) + geom_histogram(bins = 30, fill="#0072B2", comperc14_24.hist <- ggplot(driving.df, aes(x = vehicmilespc)) + geom_histogram(bins = 30, fill="#0072B2", aes(x = vehicmilespc)) + geom_histogram(bins = 30, fill="#00
```

Univariate Analysis of key Variables

The distribution looks approximately normal with some tail for totfatrte, unem, and vehiclemilespc. It looks normal with higher slope at the top and lower slope at the bottom for perc14 - 24.

Next, we examine the bivariate relationship between some of the important explanatory variables and fatality rate.

```
totfatrte.unem.scatter <- ggplot(driving.df, aes(unem, totfatrte)) +
  geom_point() +
  geom_smooth(method = "lm", formula = y ~ x, se = FALSE) + theme(axis.text.x = element_text(axis.text))
  theme(plot.title = element_text(size = 10, hjust = 0.5)) + theme(legend.position = "none")
totfatrte.perc14_24.scatter <- ggplot(driving.df, aes(perc14_24, totfatrte)) +
  geom_point() +
  geom_smooth(method = "lm", formula = y ~ x, se = FALSE) + theme(axis.text.x = element_text(axis.text))
  theme(plot.title = element_text(size = 10, hjust = 0.5)) + theme(legend.position = "none")
totfatrte.vehicmilespc.scatter <- ggplot(driving.df, aes(vehicmilespc, totfatrte)) +

geom_boxplot(aes(fill = factor(bacall))) + xlab("bac 1=.1,2=.08") + theme(axis.text.x = element_text(size = 10, hjust = 0.5)) + theme(legend.position = "none")

grid.arrange( totfatrte.bac10.box, totfatrte.perse.box, totfatrte.sbprim.box, totfatrte.sl70ple
```

Bivariate Analysis of key Variables

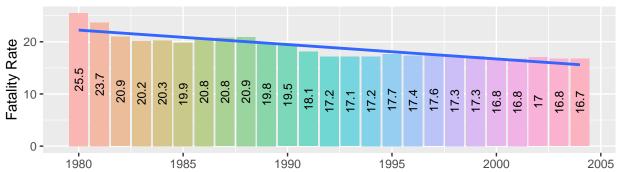

Note that fractions are rounded for representing box plots. We see that blood alcohol limit 10 has a muted effect while per se and primary seatbelt laws have reducing effect on the fatality rate. In addition, fatality rate with bac08 is slightly lower than bac10. Also note the higher fatality rate on the states with speed limit 70 and above or none. We are also exploring the relationship between fatality rate and demographic variables unem, $perc14_24$ and vehicmilespc to understand the impact.

Then, to examine both the average fatality pattern over the years, and individual fixed effect of US States across time, we'll analyze the aggregate of traffic laws in US across time and across states.

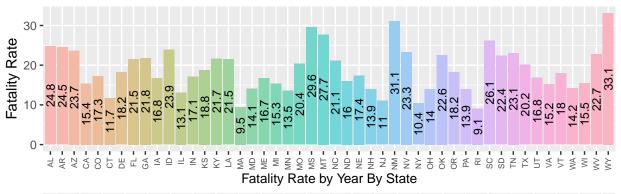

Below we analyze the fatality rate change by year and overall change by state .

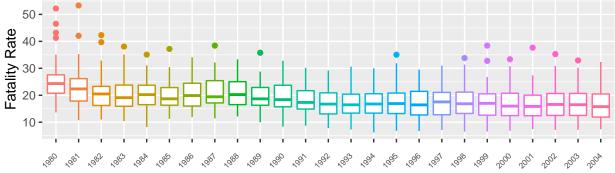

```
#fatality change by year
traffic.yearly.aggr <- data %>% group_by(year) %>% summarise_at(vars(totfatrte, nghtfatrte,
#fatality change by state
traffic.state.perc.aggr <- data.with.name ">" group_by(shortname) ">" summarise_at(vars(totfat:
year.plot <- ggplot(traffic.yearly.aggr, aes(year, totfatrte)) +</pre>
    geom_bar(aes(fill = factor(year)), position = "dodge", stat="identity") + ggtitle("Average Formula | geom_bar(aes(fill = factor(year)), position = "dodge", stat="identity") + ggtitle("Average Formula | geom_bar(aes(fill = factor(year)), position = "dodge", stat="identity") + ggtitle("Average Formula | geom_bar(aes(fill = factor(year)), position = "dodge", stat="identity") + ggtitle("Average Formula | geom_bar(aes(fill = factor(year)), position = "dodge", stat="identity") + ggtitle("Average Formula | geom_bar(aes(fill = factor(year)), position = "dodge", stat="identity") + ggtitle("Average Formula | geom_bar(aes(fill = factor(year)), position = "dodge", stat="identity") + ggtitle("Average Formula | geom_bar(aes(fill = factor(year)), position = "dodge"), stat="identity") + ggtitle("Average Formula | geom_bar(aes(fill = factor(year)), position = geom_bar(aes(fill = factor(year)), positi
    #geom_abline(intercept, slope, linetype, color, size) +
    geom_smooth(method = "lm", formula = y ~ x, se = FALSE) + geom_text(data = traffic.yearly.ag
    theme(plot.title = element_text(size = 10, hjust = 0.5)) + theme(legend.position = "none") +
state.plot <- ggplot(traffic.state.perc.aggr, aes(shortname, totfatrte)) +</pre>
    geom_bar(aes(fill = factor(shortname)), position = "dodge", stat="identity") + ggtitle("Average")
    scale_fill_hue(c=45,l=80) + theme(plot.title = element_text(size = 8, hjust = 0.5)) +
    theme(axis.text.x = element_text(angle = 90, size = 6, vjust = 0.5, hjust=1)) +
    theme(plot.title = element_text(size = 10, hjust = 0.5)) + theme(legend.position = "none") +
conditional_plot = function(data, plotvar, condvar, title) {
    g <- ggplot(data, aes(as.factor(condvar), plotvar, color = as.factor(condvar)))</pre>

grid.arrange(year.plot, state.plot, nrow = 2, ncol = 1);grid.arrange(cplot.1, cplot.2, nrow =
```

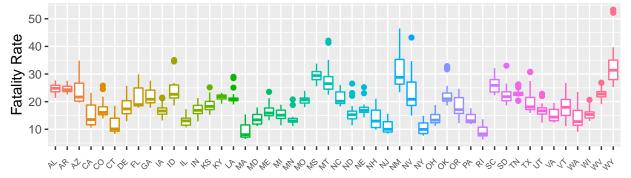

Average Fatality rate By state

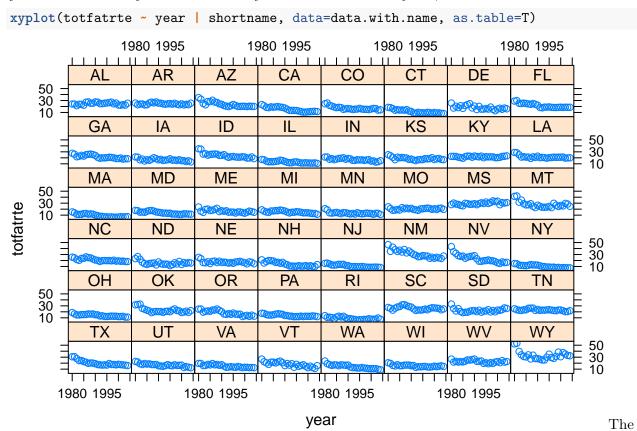

Fatality Rate by State By Year

We can see that the fatality rate is largely decreasing from 1980 to 2004. The overall fatality rates range from ~9 to ~34 between states. Wyoming, New Mexico, Mississippi, Montana, and South Carolina are the states with highest fatality rates while New York, New Jersey and Rhode Island

are the states with lowest fatality rates. The pattern shows that the states with more rural roads have higher fatality rates - the geography and road conditions are thus important omitted variables in the dataset. In addition, the fatality split by cause (drunk driving, speeding) by state by year could be an important predictor. Another omitted variable could be the a measure of compliance to the traffic laws - speed limit, seat belt - at the state level.

The boxplots graph shows there is heterogeneity across states, but very little heterogeneity across years. Next we analyze how the fatality rates varied over the years, in individual states.

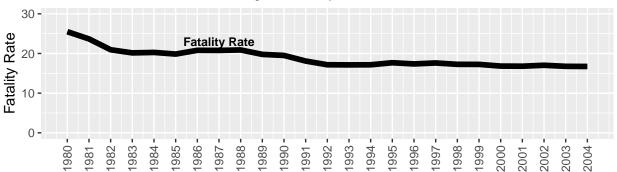

above xyplot confirms that most of the States shows an overall decrease in the traffic fatality rate, except states like *Mississippi*. We can see that New Mexico(NM) and Wyoming(WY) has high variance in the data, with NM consistently reducing the traffic fatality rate over years. However, WY reduced the fatality rate from 80's to mid 90's and had a gradual increase after. One interesting point is that the traffic fatality rate is not dependent on the state area or population - the top 2 states with size and population, *Texas* and *California*, are not among the top states in traffic fatality rate.

Below, we explore how the traffic laws over the years across states, and whether they show a correlation with fatality rate. We first plot the fatality rate over years, and then plot the count of states that adopt the traffic laws, grouped by year and specific law. We hypothesize that the fatality rate is influenced the most by drinking and overspeeding and proceed to examine the applicable laws.

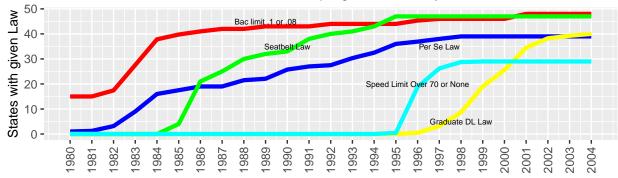

```
# summarize the number of states adopting specific traffic laws
data <- data %>% mutate(sball = case_when(sbprim + sbsecon >= 0.5 ~ 1,TRUE ~ 0 ))
bac.df <- data %>% group_by(year) %>%
```

```
summarise(bac10 = sum(bac10), bac08 = sum(bac08), bac.all = sum(bac08 + bac10), perse = sum(persolution)
bac.plot.f <- ggplot(bac.df, aes(x = year)) +
    geom_line(aes(y=totfatrte, color='totfatrte'), size = 2, group = 1) + ylim(0,30)+
    scale_x_continuous(breaks = seq(min(bac.df$year), max(bac.df$year), 1)) + theme(axis.text.x = annotate("text", x = 1987, y = 23, label = "Fatality Rate", size = 3, fontface = "bold") +
    theme(plot.title = element_text(size = 10, hjust = 0.5)) + theme(legend.position = "none")
bac.plot <- ggplot(bac.df, aes(x = year)) +
    geom_line(aes(y = bac.all, color='bac.all'), size = 1.5, group = 1) + geom_line(aes(y=perse, geom_line(aes(y=sball, color='sball'), size = 1.5, group = 1) + geom_line(aes(y=gdl, color='yealues = c(bac.all="red", perse="blue", sball="green", gdl = "yellow", sl70plus = "cyan x = "",size = 2) +
    annotate("text", x = 1998, y = 5, label = "Graduate DL Law", size = 2) + annotate("text", x = annotate("text", x = 1990, y = 35, label = "Seatbelt Law", size = 2) + annotate("text", x = annotate("text", x = 1989, y = 45, label = "Bac limit .1 or .08", size = 2) + theme(plot.tit)
grid.arrange(bac.plot.f, bac.plot, nrow = 2, ncol = 1)</pre>
```

Changes in Fatality Rate Over Time

Over the years, more states are adopting stricter alcohol limits. In 2004, over 45 states have a bac limit of 0.08 or 0.1, compared to ~10 in 1980. Similarly, ~40 states have adopted the Per Se law and Graduate DL law in 2004 compared to 0 states in 1980. We see a similar trend in seatbelt adoption as well. This is consistent with the decrease in fatality rates over time that observed before. Regarding speed limit, states had lower speed limit in 1980 - however, the speed limits were more

relaxed in the later years as can be seen by the increase in the number of states with speed limit 70 or above, as seen in the above graph.

Lets proceed to examine the individual state behavior in the panel. First, we'll examine how the traffic fatality rates changed over years for the first 3 States from the top and bottom of the fatality rate scale.

```
#Top 3 and Bottom 3 states in overall fatality scale
traffic.state.aggr <- data.with.name %>% group_by(shortname) %>% summarise_at(vars(totfat,
top.3.fatalities <- traffic.state.perc.aggr %>% filter(rank(desc(totfatrte))<=3) %>% arrange(stata.top.3.fatalities <- traffic.state.perc.aggr %>% filter(rank((totfatrte))<=3) %>% arrange(stata.top.filtered <- data.with.name %>% filter(shortname %in% c("WY"))
data.bottom.filtered <- data.with.name %>% filter(shortname %in% c("RI"))
data.merged <- union(data.top.filtered,data.bottom.filtered)

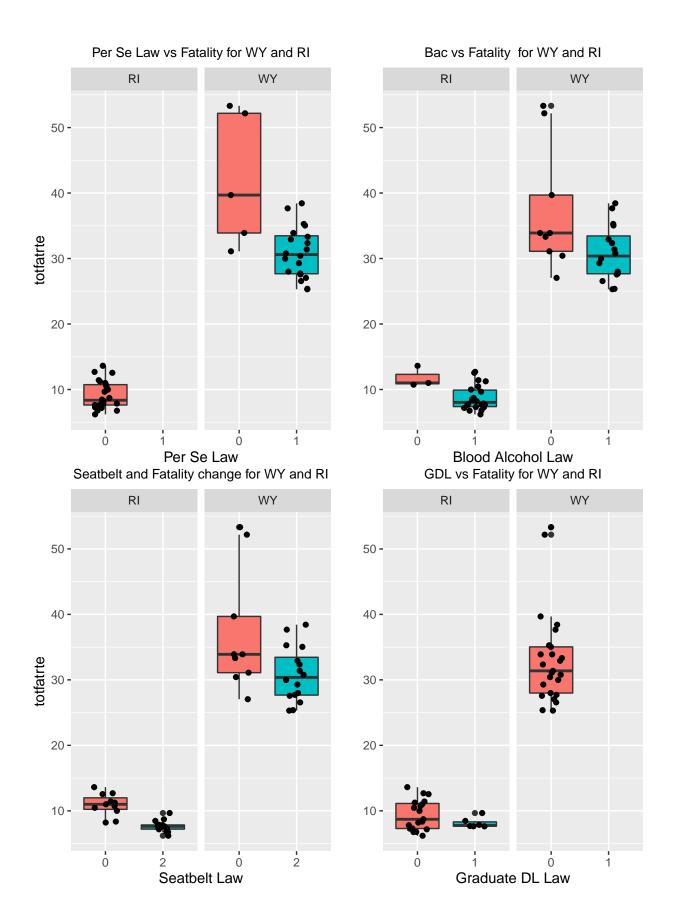

cbind(top.3.fatalities[,1:2],bottom.3.fatalities[,1:2])

## top3states totfatrte bottom3states totfatrte</pre>
```

```
top3states totfatrte bottom3states totfatrte
## 1
              WY
                   33.1408
                                        RΙ
                                               9.0900
## 2
                   31.0608
                                               9.4512
              NM
                                        MA
## 3
                   29.5548
              MS
                                        NY
                                              10.4380
```

The top 3 are Wyoming, New Mexico and Mississippi. The bottom 3 are Rhode Island, New York and Massachussets. We see that the fatality rate in Wyoming is nearly 4 times as high as in Rhode Island in 2004. Below, we see the how the fatality rate varies for seat belt, bac each state across years.

```
df.transformed <- data.merged %>% mutate( perse = case_when(perse >= 0.5 ~ 1,TRUE ~ 0),bacard g.1 <- ggplot(df.transformed, aes(as.factor(perse), totfatrte)) + geom_boxplot(aes(fill = factor g.2 <- ggplot(df.transformed, aes(as.factor(bacat), totfatrte)) + geom_boxplot(aes(fill = factor g.3 <- ggplot(df.transformed, aes(as.factor(seatbelt), totfatrte)) + geom_boxplot(aes(fill = factor g.4 <- ggplot(df.transformed, aes(as.factor(gdl), totfatrte)) + geom_boxplot(aes(fill = factor grid.arrange(g.1, g.2, nrow = 1, ncol = 2); grid.arrange(g.3, g.4, nrow = 1, ncol = 2)
```

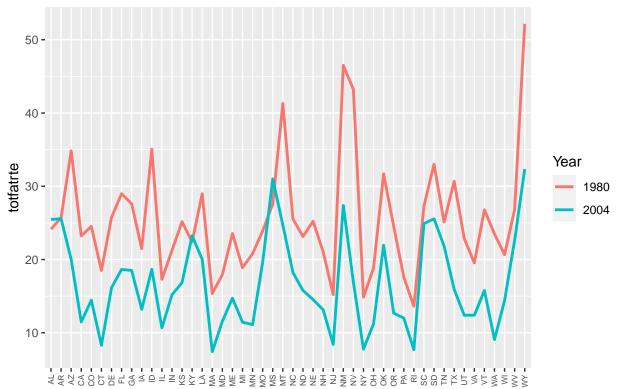

In the above graphs, seatbelt=1 indicates the the states followed the primary or secondary seatbelt laws for more than half of the year. Similar logic is applied to blood alcohol laws, Per Se and Gdl laws. We can see that WY has lower fatality rate in the years they adopted the Per Se, Bac, and Seatbelt laws. They have not adopted the Gdl law as of 2004. Rhode Island shows a similar pattern, eventhough the fatality rate was already low.

Now we will look at how fatality rate differs between 1980 and 2004 for each state.

```
df.80.04 <- data.with.name %>% filter(year %in% c('1980','2004')) %>% dplyr::select(year,shorts
ggplot(df.80.04, aes(shortname, totfatrte, group = year, colour = as.factor(year))) +
   geom_line(aes(y=totfatrte), size = 1) + ggtitle("Fatality Rates for 1980 and 2004 By State")
```

For most of the states, fatality rate in 2004 is less than 1980 barring exceptions like Arkansas(AR) and Mississippi(MS). States show more variance in 1980 than in 2004.

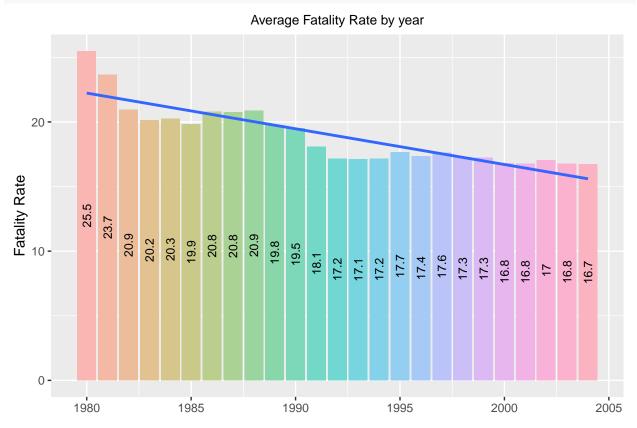

Thus both the overall and state level EDA indicates that there is a reduction in fatality rate that is consistent with traffic laws adoption. However the actual impact of the traffic laws adoption, and the demographic variables on fatality rate can be assessed only through the detailed regression analysis below.

2. (15%) How is the our dependent variable of interest *totfatrte* defined? What is the average of this variable in each of the years in the time period covered in this dataset? Estimate a linear regression model of *totfatrte* on a set of dummy variables for the years 1981 through 2004. What does this model explain? Describe what you find in this model. Did driving become safer over this period? Please provide a detailed explanation.

The dependent variable totfatrte is defined as the total fatalities per 100,000 population, grouped by

the index variables year and state. The average of this totfatrte variable per year is computed for EDA in variable traffic.yearly.aggr and plotted using year.plot.

year.plot

Let's estimate the linear regression for the dummy variables from 1981 to 2004 below.

```

This is a pooled OLS model that explains the impact of time on the total fatality rate. The year dummy variables are highly statistically significant except for 1981. We see total fatality rate trending down with time and it proves that the *driving became safer over this period*. We see that compared to 1980, for each year we have lower fatality rate. The coefficients also indicate that compared to fatality rate between 83 and 85, we see a higher fatality rate for years 86 to 88. The adjusted R² 0.1098 indicates the model is not a good fit. Diagnostic plots (not shown here due to space constraints) indicate that residuals are not normally distributed. Detailed explanation of the pooled OLS model is given in question 4.

3. (15%) Expand your model in Exercise 2 by adding variables bac08, bac10, perse, sbprim, sbsecon, sl70plus, gdl, perc14_24, unem, vehicmilespc, and perhaps transformations of some or all of these variables. Please explain carefully your rationale, which should be based on your EDA, behind any transformation you made. If no transformation is made, explain why transformation is not needed. How are the variables bac8 and bac10 defined? Interpret the coefficients on bac8 and bac10. Do per se laws have a negative effect on the fatality rate? What about having a primary seat belt law? (Note that if a law was enacted sometime within a year the fraction of the year is recorded in place of the zero-one indicator.)

Is Transformation needed?

First, we looked at the predicted variable *totfatrte* for possible transformations. EDA showed that the variale is already weighted by state population and ranged from ~6 to ~50, and was normally distributed. Hence we did not apply any transformations on the variable.

The variables bac08, bac10, perse, sbprim, sbsecon, sl70plus, gdl define the year in which the specific law became effective. It ranges from 0-1 with decimals as the law could change in the middle of the year. One possible transformation is to round up the fractions into 0 or 1 - but we choose to not round them up, as we will lose precision if the law was adopted in the middle of the year.

Variables $perc14_24$, unem, vehicmilespc are already normalized and so no transformation is necessary. Note that vehicmilespc is a candidate for log transformation - but because the variable is already a rate, and we lose interpretability with log transformation, we retain the original format.

Definition of bac08 and bac10 variables and their interpretation

bac10 is defined as the blood alcohol limit of .10 and bac08 is defined as the blood alcohol limit of .08. Both the variables bac08 and bac10 have the negative coefficients of -2.498 and -1.418 respectively. They are statistically significant and it implies that they have a strong negative correlation to the total fatality rate. If we come up with a stricter law and decrease the blood alcohol limit to .10 then the fatalities rate decreases more.

Effect of perse law on fatality rate

Yes. perse variable has a statistically significant negative correlation with the total fatality rate. The coefficient value is -0.6201 which implies a small change in the rate.

Effect of primary seat belt law on fatality rate

We are not able to find any statistically significant effect of the primary seat belt law on the fatality rate based on the regression coefficients shown below.

4. (15%) Reestimate the model from *Exercise 3* using a fixed effects (at the state level) model. How do the coefficients on *bac08*, *bac10*, *perse*, *and sbprim* compare with the pooled OLS estimates? Which set of estimates do you think is more reliable? What assumptions are needed in each of these models? Are these assumptions reasonable in the current context?

Coeefficients comparison for bac08, bac10, perse, and sbprim between pooled OLS and Fixed effects model

Coefficients have gone down for the bac08, bac10, perse, and sbprim from -2.498, -1.418, -0.62, -0.07533 for the pooles OLS model to -1.437, -1.062, -1.152, -1.227 for the fixed effects model respectively. Furthermore sbprim has become statistically significant in the Fixed effects model.

Model reliability and assumptions

d89

Fixed effects model is more reliable than the pooled OLS model as it considers the panel data into account and models the total fatality rate of each state over time.

Pooled OLS model assumes that the individual specific effects are uncorrelated with the independent variables. This is a wrong assumption as there will be correlation between different observations within the same state. But Fixed effects model assumes that the individual specific effect are correlated with the independent variables and therefore is more reasonable in the current context than the pooled OLS model.

Comparing the random effect model to the fixed effect model using the Hausman's test.

```
phtest(model.fe, model.re)
```

```
##
## Hausman Test
##
## data: totfatrte ~ d81 + d82 + d83 + d84 + d85 + d86 + d87 + d88 + d89 + ...
## chisq = 148.69, df = 34, p-value = 2.727e-16
## alternative hypothesis: one model is inconsistent
```

p-value is statistically significant and we can reject the null hypothesis that the unobserved fixed effects are uncorrelated with the explanatory variables. Therefore, We will prefer the Fixed effect model instead of the random effects model in this scenario.

6. (10%) Suppose that *vehicmilespc*, the number of miles driven per capita, increases by 1,000. Using the FE estimates, what is the estimated effect on *totfatrte*? Please interpret the estimate.

The coefficient for the *vehicmilespc* variable is 0.00094005 using the FE estimates and it is highly statistically significant. In other words, There will be an increase of 0.94 fatalities per 100k for an increase of 1000 vehicle miles driven per capita.

7. (5%) If there is serial correlation or heteroskedasticity in the idiosyncratic errors of the model, what would be the consequences on the estimators and their standard errors?

If there is Serial correlation then it will not affect the unbiasedness or consistency of OLS estimators, but it does affect their efficiency. With positive serial correlation, the OLS estimates of the standard errors will be smaller than the true standard errors. This will lead to the conclusion that the parameter estimates are more precise than they really are. There will be a tendency to reject the null hypothesis when it should not be rejected. Much of the time serial correlation is viewed as the most important problem, because it usually has a larger impact on standard errors and the efficiency of estimators than does heteroskedasticity. The presence of heteroskedasticity, while not causing bias or inconsistency in the coefficients does invalidate the usual standard errors, t statistics, and F statistics.
